## How Money Matters

Over the past 15 years the quantity of money has largely disappeared from policy discussions and the economic models used to provide monetary policy advice. Most central banks that were targeting money growth have stopped doing so. We no longer ask which measure of money is the "correct" indicator for monetary policy. Instead, we directly examine measures of inflation and output for guidance about setting the stance of monetary policy.

Yet, money still matters. It plays three fundamental roles in the economy: a medium of exchange, a store of value, and the unit of account. Traditionally, monetary policy was viewed as operating through the medium of exchange or the store of value, or both. We focused on M1 when we thought the medium of exchange role was dominant, because the funds in M1 are primarily used to make transactions. We focused on M2 when we thought that the wealth effect was important or that close substitutes for M1 would be informative.

Since 1982, however, measures of the quantity of money have provided little useful information about the near-term outlook for spending or inflation. Money growth has remained highly variable even as inflation has become less variable. As the chart shows, the variability of inflation, calculated as the standard deviation of quarterly percent changes in the CPI, declined by half between 1970-82 and 19832003. But the variability of the money stock, measured using either M1 or M2, actually went up a bit.

This disconnect between the variability of inflation and money growth is partly due to the success of policy in reducing inflation and causing expectations of future inflation to become more stable. In this environment, the Federal Reserve has been able to keep its federal funds target rate fixed for months at a time. When the funds rate is fixed, the short-run money supply is perfectly elastic with respect to the interest rate and all changes in money demand are perfectly accommodated.

The role of money as our unit of account, the dollar, is at center stage in monetary policy today. Our models and our discussions focus not on the quantity of money but on the purchasing power of the dollar. More uncertainty about the value of a dollar, both now and in the future, causes consumers, investors, and business managers to make mistakes that reduce economic efficiency and living standards. That is, changes in expected inflation and errors that result when actual inflation deviates from previous expectations cause economic inefficiencies. Of course, many aspects of our economy are not fully indexed for inflation. A higher inflation rate, for example, results in a higher effective tax rate on capital gains. Higher inflation also causes more uncertainty about inflation.

In fact, an important channel by which the Federal Reserve stabilizes the value of a dollar is through expectations of future inflation, the main channel through which monetary policy affects the real economy. We do not have to pay attention to the quantity of money today because policymakers are paying attention to its price, by focusing on inflation and inflation expectations.
-William T. Gavin

Standard Deviation of Money Growth and Inflation

NOTE: The standard deviations are calculated from quarterly data and reported at annual rates.

## Conventions used in this publication:

1. Unless otherwise indicated, data are monthly.
2. Shaded areas indicate recessions, as determined by the National Bureau of Economic Research.
3. Percent change at an annual rate is the simple, not compounded, monthly percent change multiplied by 12 . For example, using consecutive months, the percent change at an annual rate in x between month $t-1$ and the current month $t$ is: $\left[\left(x_{t} / x_{t-1}\right)-1\right] \times 1200$. Note that this differs from National Economic Trends. In that publication, monthly percent changes are compounded and expressed as annual growth rates.
4. The percent change from year ago refers to the percent change from the same period in the previous year. For example, the percent change from year ago in $x$ between month $t-12$ and the current month $t$ is: $\left[\left(x_{t} / x_{t-12}\right)-1\right] \times 100$.

## Definitions

M1: The sum of currency held outside the vaults of depository institutions, Federal Reserve Banks, and the U.S. Treasury; travelers checks; and demand and other checkable deposits issued by financial institutions (except demand deposits due to the Treasury and depository institutions), minus cash items in process of collection and Federal Reserve float.

MZM (money, zero maturity): M2 minus small-denomination time deposits, plus institutional money market mutual funds (that is, those included in M3 but excluded from M2). The label MZM was coined by William Poole (1991); the aggregate itself was proposed earlier by Motley (1988).

M2: M1 plus savings deposits (including money market deposit accounts) and small-denomination (under $\$ 100,000$ ) time deposits issued by financial institutions; and shares in retail money market mutual funds (funds with initial investments under $\$ 50,000$ ), net of retirement accounts.

M3: M2 plus large-denomination (\$100,000 or more) time deposits; repurchase agreements issued by depository institutions; Eurodollar deposits, specifically, dollar-denominated deposits due to nonbank U.S. addresses held at foreign offices of U.S. banks worldwide and all banking offices in Canada and the United Kingdom; and institutional money market mutual funds (funds with initial investments of $\$ 50,000$ or more).

Bank Credit: All loans, leases, and securities held by commercial banks.
Domestic Nonfinancial Debt: Total credit market liabilities of the U.S. Treasury, federally sponsored agencies, state and local governments, households, and nonfinancial firms. End-of-period basis.

Adjusted Monetary Base: The sum of currency in circulation outside Federal Reserve Banks and the U.S. Treasury, deposits of depository financial institutions at Federal Reserve Banks, and an adjustment for the effects of changes in statutory reserve requirements on the quantity of base money held by depositories. This series is a spliced chain index; see Anderson and Rasche (1996a,b, 2001, 2003).

Adjusted Reserves: The sum of vault cash and Federal Reserve Bank deposits held by depository institutions and an adjustment for the effects of changes in statutory reserve requirements on the quantity of base money held by depositories. This spliced chain index is numerically larger than the Board of Governors' measure, which excludes vault cash not used to satisfy statutory reserve requirements and Federal Reserve Bank deposits used to satisfy required clearing balance contracts; see Anderson and Rasche (1996a, 2001, 2003).

Monetary Services Index: An index that measures the flow of monetary services received by households and firms from their holdings of liquid assets; see Anderson, Jones, and Nesmith (1997). Indexes are shown for the assets included in M2, with additional data at research.stlouisfed.org $/ \mathrm{msi} / \mathrm{index} . \mathrm{html}$.

Note: M1, M2, M3, Bank Credit, and Domestic Nonfinancial Debt are constructed and published by the Board of Governors of the Federal Reserve System. For details, see Statistical Supplement to the Federal Reserve Bulletin, tables 1.21 and 1.26. MZM, Adjusted Monetary Base, Adjusted Reserves, and Monetary Services Index are constructed and published by the Research Division of the Federal Reserve Bank of St. Louis.

## Notes

Page 3: Readers are cautioned that, since early 1994, the level and growth of M1 have been depressed by retail sweep programs that reclassify transactions deposits (demand deposits and other checkable deposits) as savings deposits overnight, thereby reducing banks' required reserves; see Anderson and Rasche (2001) and research.stlouisfed.org/aggreg/swdata.html. Primary Credit Rate, Discount Rate, and Intended Federal Funds Rate shown in the chart Reserve Market Rates are plotted as of the date of the change, while the Effective Federal Funds Rate is plotted as of the end of the month. Interest rates in the table are monthly averages from the Board of Governors H. 15 Statistical Release. The Treasury Yield Curve shows constant maturity yields calculated by the U.S. Treasury for securities with 3 months and 1,2,3,5, 7, and 10 years to maturity. Daily data and descriptions are available at research.stlouisfed.org/fred2/. See
also Statistical Supplement to the Federal Reserve Bulletin, table 1.35. The 30-year constant maturity series was discontinued by the Treasury as of February 18, 2002.

Page 5: Checkable Deposits is the sum of demand and other checkable deposits. Savings Deposits is the sum of money market deposit accounts and passbook and statement savings. Time Deposits have a minimum initial maturity of 7 days. Large Time Deposits are deposits of $\$ 100,000$ or more. Retail and Institutional Money Market Mutual Funds are as included in M2 and the non-M2 component of M3, respectively.
Page 7: Excess Reserves plus RCB (Required Clearing Balance) Contracts equals the amount of deposits at Federal Reserve Banks held by depository institutions but not applied to satisfy statutory reserve requirements. (This measure excludes the vault cash held by depository institutions that is not applied to satisfy statutory reserve requirements.) Consumer Credit includes most short- and intermediate-term credit extended to individuals. See Statistical Supplement to the Federal Reserve Bulletin, table 1.55.

Page 8: Inflation Expectations measures include the quarterly Federal Reserve Bank of Philadelphia Survey of Professional Forecasters, the monthly University of Michigan Survey Research Center's Surveys of Consumers, and the annual Federal Open Market Committee (FOMC) range as reported to the Congress in the February Humphrey-Hawkins Act testimony each year. Beginning February 2000, the FOMC began using the personal consumption expenditures (PCE) price index to report its inflation range and therefore is not shown on this graph. CPI Inflation is the percentage change from a year ago in the consumer price index for all urban consumers. Real Interest Rates are ex post measures, equal to nominal rates minus CPI inflation.
Page 9: FOMC Intended Federal Funds Rate is the level (or midpoint of the range, if applicable) of the federal funds rate that the staff of the FOMC expected to be consistent with the desired degree of pressure on bank reserve positions. In recent years, the FOMC has set an explicit target for the federal funds rate.

Page 10: Federal Funds Rate and Inflation Targets shows the observed federal funds rate, quarterly, and the level of the funds rate implied by applying Taylor's (1993) equation

$$
f_{t}^{*}=2.5+\pi_{t-1}+\left(\pi_{t-1}-\pi^{*}\right) / 2+100 \times\left(y_{t-1}-y_{t-1}^{P}\right) / 2
$$

to five alternative target inflation rates, $\pi^{*}=0,1,2,3,4$ percent, where $f_{t}^{*}$ is the implied federal funds rate, $\pi_{t-1}$ is the previous period's inflation rate (PCE) measured on a year-over-year basis, $y_{t-1}$ is the $\log$ of the previous period's level of real gross domestic product (GDP), and $y_{t-1}^{P}$ is the log of an estimate of the previous period's level of potential output. Potential Real GDP is as estimated by the Congressional Budget Office.

Monetary Base Growth and Inflation Targets shows the quarterly growth of the adjusted monetary base (modified to include an estimate of the effect of sweep programs) implied by applying McCallum's $(1988,1993)$ equation

$$
\begin{aligned}
\Delta M B_{t}^{*} & =\pi^{*}+(10 \text {-year moving average growth of real GDP }) \\
& -(4 \text {-year moving average of base velocity growth })
\end{aligned}
$$

to five alternative target inflation rates, $\pi^{*}=0,1,2,3,4$ percent, where $\Delta M B_{t}{ }^{*}$ is the implied growth rate of the adjusted monetary base. The 10 -year moving average growth of real GDP for a quarter $t$ is calculated as the average quarterly growth during the previous 40 quarters, at an annual rate, by the formula $\left(\left(y_{t}-y_{t-40}\right) / 40\right) \times 400$, where $y_{t}$ is the $\log$ of real GDP. The 4 -year moving average of base velocity growth is calculated similarly. To adjust the monetary base for the effect of retail-deposit sweep programs, we add to the monetary base an amount equal to 10 percent of the total amount swept, as estimated by the Federal Reserve Board staff. These estimates are imprecise, at best. Sweep program data are found at research.stlouisfed.org/aggreg/swdata.html.

Page 11: Implied One-Year Forward Rates are calculated by this Bank from Treasury constant maturity yields. Yields to maturity, $R(m)$, for securities with $m=1, \ldots, 10$ years to maturity are obtained by linear interpolation between reported yields. These yields are smoothed by fitting the regression suggested by Nelson and Siegel (1987),

$$
R(m)=\mathrm{a}_{0}+\left(\mathrm{a}_{1}+\mathrm{a}_{2}\right)\left(1-\mathrm{e}^{-m / 50}\right) /(m / 50)-\mathrm{a}_{2} \times \mathrm{e}^{-m / 50}
$$

and forward rates are calculated from these smoothed yields using equation (a) in table 13.1 of Shiller (1990),

$$
f(m)=[D(m) R(m)-D(m-1)] /[D(m)-D(m-1)]
$$

where duration is approximated as $D(m)=\left(1-e^{-R(m) \times m}\right) / R(m)$. These rates are linear approximations to the true instantaneous forward rates; see Shiller (1990). For a discussion of the use of forward rates as indicators of inflation expectations, see Sharpe (1997). Rates on 3-Month Eurodollar Futures and Rates on Selected Federal Funds Futures Contracts trace through time the yield on three specific contracts. Rates on Federal Funds Futures on Selected Dates displays a single day's snapshot of yields for contracts expiring in the months shown on the horizontal axis. Inflation-Indexed Treasury Securities are yields on the most recently issued inflation-indexed securities of 10 - and 30-year original maturities. Inflation-Indexed 10-Year Government Notes shows the yield of an inflation-indexed note that is scheduled to mature in approximately (but not greater than) 10 years. The current French note has a maturity date of $7 / 25 / 2013$, the current U.K. note has a maturity date of 8/16/2013 , and the current U.S. note has a maturity date of $1 / 15 / 2014$. InflationIndexed Treasury Yield Spreads and Inflation-Indexed 10-Year Government Yield Spreads equal the difference between the yields on the most recently issued inflation-indexed securities and the unadjusted security yields of similar maturity.

Page 12: Velocity (for MZM and M2) equals the ratio of GDP, measured in current dollars, to the level of the monetary aggregate. MZM and M2 Own Rates are weighted averages of the rates received by households and firms on the assets included in the aggregates. Prior to 1982, the 3-month T-bill rates are secondary market yields. From 1982 forward, rates are 3-month constant maturity yields.

Page 13: Real Gross Domestic Product is GDP as measured in chained 2000 dollars. The Gross Domestic Product Price Index is the implicit price deflator for GDP, which is defined by the Bureau of Economic Analysis, U.S. Department of Commerce, as the ratio of GDP measured in current dollars to GDP measured in chained 2000 dollars.

Page 14: Investment Securities are all securities held by commercial banks in both investment and trading accounts.
Page 15: Inflation Rate Differentials are the differences between the foreign consumer price inflation rates and year-over-year changes in the U.S. all-items Consumer Price Index.

Page 17: Treasury Yields are Treasury constant maturities as reported in the Board of Governors of the Federal Reserve System's H. 15 release.
